Relative Efficiency of the 3 methods

- Therefores solving (n+1) x (n+1) linear system to compute coefficients of interpolating polynomial evaluation of resulting polynomial is reasonable if rewritten in nested form (Honer's Rule).

 Vandermonde matrix is usually poorly conditioned
- if n is large

 2 Constructing lagrange basis polynomial is

essentially free. The ith coefficient is just y: for the ith data point.

- Evaluation is expensive at non-interpolating points.

 It ainly used only in proofs of theorems. Not
 very practical.
- (3) Coefficients are not expensive to compute with divided difference table and resulting polynomial is easily written in nested form for efficient evaluation

which method is best if we need to add data points? ie: add (3,141) to previous example

- (1) Add column and row to V, refactor matrix, condition is potentially worsened
 - 2) Construction Still Free. But each basis function changes and evaluation becomes even more expensive.
 - 3) Just add row and column to divided differences table, but most calculations are reused
